## INTRODUCTION

## Project Aims and Methods

Over 8 weeks in the early summer of 2004, the third season of a five-year project of archaeological investigations at Skálholt was successfully completed. The project's overall aims encompass a full investigation and presentation of the post-medieval settlement as it was prior to its abandonment and at the height of its cultural influence in Iceland (c. 1630-1785). The project will provide key information about the material culture in the post-medieval period in Iceland, particularly offering a baseline study in wealth and status and how this was expressed among an elite community in the country. A more detailed background to the site and previous archaeological work can be found in the first and second reports (see Lucas 2002; 2004).

The specific aims of the 2004 season were:

- to complete the excavation of all rooms and features on the eastern side of the settlement including the main corridor, back to early $17^{\text {th }}$ century levels
- to continue work on the western part of the settlement
- to expand investigations on the midden slope, south of the settlement

The excavation team usually comprised 10-11 members at any one time, and included both students and professional archaeologists. The same excavation and recording methods were employed as the previous season, with minor modifications. The site was re-turfed at the end of the season for purposes of protection and presentation as with previous seasons. In addition, further geophysical surveying was conducted on the westernmost area of the farm to see if further structures could be located as clearly as those in 1999.

An extensive outreach programme, integrated with the project from the very first season, was maintained, although with few further developments. Three guided tours were offered on weekends, with a children's open day on one of them; periodic press releases were given and the excavation, as in previous years, received positive media
attention. The exhibition of finds was relocated to the school at Skálholt and expanded with more thematic display boards, with information on material culture at Skálholt in the $18^{\text {th }}$ century in relation to school life, clothing, eating and drinking and smoking. It is hoped this will be further expanded to form a major exhibition of the archaeology of everyday life at Skálholt.

## Contributors and Acknowledgements

The project would not be possible without the support and collaboration of a number of people. The Millennium Fund (Kristnihátíðarsjóður) provided the necessary financial support to conduct the work with its generous grant. Thanks must also go to the Bishop of Skálholt, Sigurður Sigurðarson, and the Rector Bernharður Guðmundsson for their tremendous support and help at all stages of the project. Also thanks to the farmer at Skálholt, Guttormur Bjarnason for making the day to day running of the excavation so much easier and smoother, and also to the administrator Holmfríður Ingólfsdóttir, chef Bjarni Birgisson and all the staff at the hotel. The management of the research project was undertaken by Gavin Lucas, Mjöll Snæsdóttir and Orri Vésteinsson, with Barbara Guðnadóttir as the public relations manager. The excavation team comprised Andrew Hall, Auður Halldórsdóttir, Ágústa Edwald, Birna Lárusdóttir, Candy Hatherley, Cassian Hall, Dmitri Tarat, Elín Hreiðarsdóttir, Gavin Lucas (Director), Lilja Björk Pálsdóttir, Mjöll Snæsdóttir, Óskar G. Sveinbjarnarson, Sigríður Porgeirsdóttir and Sólveig Guðmundsdóttir Beck. In addition, George Hambrecht from CUNY joined the team for 3 weeks to excavate midden deposits associated with the site, and Arnar Már Vihjálmsson from Háskóli Íslands, came for 3 days to conduct a resistivity survey on the western slopes of the farm mound. On behalf of the National Museum, Graham Langford is supervising the conservation of the artefacts.

## Fieldwork Results

## Excavation of the Main Area

The main area of excavation remained the same as 2003, without any further expansion (Fig. 1), as there was more than enough work still to complete before considering enlarging the site. Most of the excavation focused on remains from $17^{\text {th }}$ to $19^{\text {th }}$ centuries, but in several places, traces of the $20^{\text {th }}$ century farm were still surviving. The eastern side of the area, whose core was originally opened in the first season in 2002, was finally completed, with excavation down to the $17^{\text {th }}$ century. Traces of earlier remains were visible beneath, but belonged to a completely different layout, and it was at this level that we decided to stop. On the western side, progress was made in uncovering more of the area stripped in 2003, but at present, different phases are still represented, with the easternmost rooms now excavated back to the $18^{\text {th }}$ and $17^{\text {th }}$ century, while the westernmost rooms still in the $19^{\text {th }}$ century.

The phasing employed is the same as the previous year and is reproduced below:

| Phase 1 | 1958-present | This covers the period after the farm mound was completely <br> abandoned and leveled, up to and including the present excavations. |
| :---: | :--- | :--- |
| Phase 2 | c.1896-1958 | This covers the period of the modern farm house and associated farm <br> buildings |
| Phase 3 | c. 1784-1896 | This covers the period after the earthquake and the relocation of the <br> school, when the settlement reverted to a small farm |
| Phase 4 | c. 1630/50-1784 | This covers the period between the great fire/rebuilding of the farm <br> and the abandonment of the school and the earthquake. |
| Phase 5 | Pre 1630 | This covers the period before the great fire. |

Figure 1. Excavation Areas

Phase 1 is not discussed below, as nothing was excavated or observed from this phase this season. Rooms and other elements of the complex were, as before given group numbers, and when a room has been greatly modified or rebuilt, it has been given a new number. A key to the groups can be found in Appendix 1.

Figure 2. The Site Hut

## Phase 5 (pre-1630)

In 2003, one room [691] with passages [421] was though to belong to this phase, both because of the date of surface finds and its anomalous position with respect to the phase 4 buildings. However subsequent excavation in 2004 shows clearly this building belongs to phase 4; further descriptions can be found in the section discussing phase 4 below. Currently, all that can be attributed to pre-1630 levels consists of traces and fragments visible from the foundation levels of phase 4 structures (Fig. 3).

## Phase 5 (pre-1630)

$25 m$
Figure3. Phase 5 features

Phase 4 (c. 1630-1784) - earlier part

Figure 4. Phase 4 features

These include some demolition or collapse layers ([1115], [1132], [1122], [1078]), but also structural elements, particularly traces of three walls; on the east site, a narrow passage with a room/passage at right-angles to it [1142] lies beneath the phase 4 school, while on the west side, part of a wall [1154] comes out beneath the phase 4 corridor at its northern end. It is likely parts of other earlier walls are visible on the western side, but until the later phases have been understood and disentangled, any earlier attribution must be postponed. Further investigation of such tantalizing remains will, unfortunately, not be a part of this project.

## Phase 4 (1630/50-1784)

This phase covers the last major period of Skálholt as an episcopal manor and school, beginning with the great re-building that took place during the mid 17th century after a fire in 1630 and up to the earthquake of 1784 when the see and school was moved to Reykjavík. Archaeologically, there are several sub-phases within this period as marked by re-building or repair recorded to elements of the complex; these have yet to be synchronized and indeed, probably occurred at different periods within this phase, so at present, no site-wide sub-phasing will be discussed, although changes to individual rooms will be described and where possible, assigned dates through associated finds and documentary sources. Figure 4 shows the site as it was in the earlier part of this phase (in the 17th century - for a plan of the 18th century, see 2004 Report). As in last year's report, discussion will proceed room by room, starting at the eastern end of the complex with the school.

Room [878] (School Room; ÁE/AFH/AH)

The school room was originally excavated in 2002, but only its later phase (room [81]; see Interim Report No.1); no subsequent work was done on this room except for the fire place [153] which was partially excavated in 2002 and again in 2003. The fireplace was from the end of 2002, realized to belong to an earlier phase of the school room, and it was not until this season that the associated room was finally excavated. The room was
slightly wider than its successor but substantially shorter, its internal dimensions being 3 x 8.1m, but on the same alignment. The walls [1058] of this earlier room are much less well preserved as essentially the same stones had been re-used to make the later room. There was a connecting door/short passage to the adjacent dormitory, as in the later phase, but also, possibly, a door to the outside, on the southern gable end. Here there was a solid stone cobbled threshold [1046], which would seem to mark an opening of some nature.

Figure 5. Excavation of the class room floor

There were two major floor layers excavated [879] and [894], both of which contained finds dating from the $17^{\text {th }}$ century. A drain [1017] ran through the center of the room, east-west, but did not seem to connect to the drain in the passage to the dormitory, and it may have acted more as a sump. The fireplace [153] lay on the eastern side in the middle of the room, and exhibited two phases, being narrowed and shortened in the later phase. As excavated, there were stratigraphic problems insofar as ash layers in the earliest phase of the fireplace seemed to interdigitate with the sub-floor leveling [947] of the main
room. It likely that there has been a lot of disturbance here, a fact supported by the very unstable nature of the deposits beneath the sub-floor make up layer, much of which may be post-depositional and possibly relate to the earthquake in 1784.

Room [733] (Dormitory; SD)

The corresponding earlier phases of the dormitory were largely excavated in 2003 (see Interim Report No.2), but some remaining parts of the floor layers [1156/1130] on the northern edge were uncovered and excavated. In addition, the connection between the western end of the dormitory and the passages both into the cathedral and the main corridor was further explored. Unfortunately the important relationships had been truncated by the $20^{\text {th }}$ century haybarn, but based on what has survived, it appears that the western end of the dormitory must have stepped up to meet the level of these passages. The passage [1269] into the cathedral was largely excavated by Kristján Eldjárn (among others) in the 1950s, but a portion survived beneath the modern reconstruction, which was built at the level of the earlier of two phases identified; the surviving portion recorded this season is probably part of this earlier phase floor (i.e. Gólf II). It consisted of parts of a flagstone floor/capping over a drain [1280] were located, which would have turned to join the drain in corridor [106], which in turn fed into the main drain of the corridor [30]. Given the height differences, the drain in the dormitory cannot have been connected to this passage drainage system, indeed it rather appeared to connect into a buried drainage system belonging to an earlier phase of the settlement. This could not be explored further due to the overlying walls of the 17th century complex.

Room [901] (Annexe; SGB)

Coming off the passage [1269] to the church on the western side, is a chamber not marked on any of the $18^{\text {th }}$ century plans; only half the room lies within the limits of excavation, the northern half lying beneath the church mound and partially excavated by Kristján Eldjárn in the 1950s. There are two phases to the room, the later phase was excavated in 2003 (room [127]), and seemed to date to the $18^{\text {th }}$ century. The earlier room
was somewhat larger, its southern and eastern wall set back from the later re-build [127]. The room as excavated measured 2.6 m long and 3.1 m wide, but assuming the doorway is central and half lies within the excavated area, we can project the full length of the room as c .5 .2 m . Floor layers were artefact-rich, and contained finds broadly dated to the late $17^{\text {th }}$ and $18^{\text {th }}$ century. A number of post pads were also preserved around the sides of the room, marking the position of roof-bearing timbers. The use of this room is currently unidentified from documentary sources, but given the density of finds, was probably living/sleeping quarters for one or more people, perhaps even someone associated with school, given its location.

Room [842] ('Sleeping Room’; SD)

In 2002, a flagstone floor room [100] was excavated which was believed to have been the infirmary; upon removal of the flagstones in 2003, an earlier, ash floor was found, and a re-analysis of the finds suggested that the later room dates to the $19{ }^{\text {th }}$ century and the earlier part to the documented infirmary, constructed sometime between 1771 and 1781 . beneath this room in 2004, an earlier building was uncovered with its long axis oriented 90 degrees the other way to the later room. This earlier room [842] is shown marked on an early-mid $18^{\text {th }}$ century plan as the 'svefnhus'. Unfortunately, the eastern half of the room was completely truncated by the haybarn, bisecting the room almost perfectly in two; what remained was the eastern half and half the doorway into the passage [106]. The extant half measured c. 2.5 m wide and 2.5 m long, suggesting an original length of c .5 m ; it was in very bad condition, much of its walls damaged probably due to the building of the later room [100], although substantial and artefact-rich floors survived, dividing into two main phases ([915] and [1011]). The entrance from the room into the passage [106] was equally disturbed, but it was from the collapse layers in here that a Frederik IV (1714) gold coin was found.

## Passage [30] (Main Corridor; EH)

The corridor was excavated down to the top of the occupation levels in 2003 but no further; a sinuous drain [1117] was exposed running the length of the passage, but all traces of the original floor/capstones [1137] to the drain had gone save in three places: large flagstones survived under a blocking wall to the southern end of the passage, at the northern exit, and on the eastern edge of the side passage [106], where the haybarn truncation. It is likely that similar sized flags occurred throughout the passage but were robbed after its abandonment. The drain fill [784/793] was excavated in 1m segments and although treated as one fill, had undoubtedly accumulated over a long period.

Figure 6. Excavation of the drain in the main corridor

The sides of the drain were overlain by small, sub-floor flagstones and turf [669], used to level the surface beneath the flagstones and these were similarly excavated on 1 m segments to control for artefact recovery. The drain sides themselves consisted of solid stone blocks and turf [1034], and this was excavated on 5m segments. Only in the side passage [106] was the drain actually cut [1106], and without lining. The drain seems to have been retained and in use for as long as the corridor, and although it shows no clear evidence of modification, the capstones [1137], which also doubled as the floor, had possibly been raised and the sub-floor leveling layer [669] added to over time. The reason being, the corridor was certainly narrowed at some point, as both part of the sub-floor leveling layer [669] and the sides of the drain [1034] continued beneath the extant walls [1283] of the corridor and abutted a lower course [1152], set back from the upper wall. Since the original walls of the corridor could not be revealed without removing the later walls - and since the later walls were probably re-built from the same stone as the earlier line, it was decided not to excavate back, but trace as far as possible the line of the earlier wall, either by visible exposure or probing. The subsequent plan suggests the original corridor was c .1 .3 m wide, later being narrowed to c .1 m .

## Room [887] (Wheystore; GL)

In 2003, a room marked as the 'syruklefi' on the 1784 plan was uncovered and partially excavated; this season it was completed and further, shown to exhibit two phases, the earliest phase shown on the earlier $18^{\text {th }}$ century perspectival plan. Documentary inventories from 1674 and 1698 refer to a whey store with two containers or 'sýruker í jörðu', and this was probably built sometime between 1630 and 1674. In its original form, the whey store [887] was a large, two-celled room with a central flagged passage [1270] leading into the main corridor. The room was 4.4 m long and 2.7 m wide, divided into two square cells cut down to an extant depth of 1.9 m , though the southern cell was deeper than the northern. Both cells had originally contained wooden vats for holding whey, but these had been dismantled when the room was re-built. Based on surviving traces, their construction appears to have consisted of a red/pink/white clay lining along the sides and base of the cut, with timber cladding forming the inside of the vat. Textiles
and horsehair had been used as caulking to seal any gaps. A very narrow ledge ran around the perimeter of the vats, and was covered with ashes; its possible the wooden lining originally extended a little higher than this surface, but otherwise the ledge could have provided a surface for throwing planks across the vat, either for walking over or covering. The ledge however certainly provided a surface for the roof supports - at each corner and at each end of a center ridge between the vats were postpads on which rested timbers for holding up the roof, three pairs in total.

Figure 7. Later phase of the whey store

Sometime in the $18^{\text {th }}$ century, one of the vats was removed and the cell backfilled, the room reduced in size to just the northern cell/vat. In this new room [583], the vat was rebuilt, but much in the same way, only this time to a shallower depth with a blue clay used to line the sides and in addition, the floor was flagged. When this re-building occurred is hard to say, as the documentary sources are ambiguous, but a 1744 description mentions
the wheystore is very old and in poor condition, and in 1747 is re-built. However, it is conceivable that the re-building of the northern vat was not simultaneous with the closure of the southern vat; stratigraphically, the difference is hard to discern, but documentary sources regarding roof supports in 1744 , indicates that the room may have already been only half its original size.

There is another store room [689] on the eastern side of the corridor, and this was excavated in 2003; however, this was probably built late in the $18^{\text {th }}$ century based on documentary sources and plans. Also on the eastern side of the corridor is the refectory [690], though this was only exposed in 2003 and was not further investigated this season. It probably dates back to the $17^{\text {th }}$ century though and hopefully will be excavated in 2005. On the eastern side of the corridor, three rooms which were originally uncovered in 2002, all originally date also to the $17^{\text {th }}$ century, though their excavation has proceeded at different rates. The southernmost, room [39] is shown as the priest's rooms and miller's rooms on the 1784 plan, but in the early-mid $18^{\text {th }}$ century, was known as the 'children's house' or 'barnhus'; excavation of this was thought to have been completed in 2003, but it is possible that we may have only uncovered its latest phase. Again, future work will hopefully resolve this question. To the north however, rooms [55] and [15] were continued this season down to $18^{\text {th }}$ and $17^{\text {th }}$ century levels (as rooms [1200] and [989] respectively), though only the northernmost room [15] was actually completed.

Room [989] (Inner Chambers; CH)

This room revealed a remarkable sequence of phases and re-builds, and continues into the $19^{\text {th }}$ century as part of the main farmhouse (as rooms [300] and [301]). However, this season, the $17^{\text {th }} / 18^{\text {th }}$ century phase was excavated - although it remains ambiguous still how old room [989] is, and it is possible that the earlier $17^{\text {th }}$ century phase still remains to be found. Finds from the occupation and construction layers are mostly $17^{\text {th }}$ century, but there is some early-mid $18^{\text {th }}$ century material as well. The chief clue that there may be an earlier phase is the presence of a blocked in doorway/passage [1266] on the eastern side which links with the main corridor - this season, only the blocking was removed (which
incorporated early-mid $18^{\text {th }}$ century finds), but this blocking predates the floor layer in room [989]. This passage is also almost certainly associated with the earlier, wider phase of the main corridor, as there was no sign of the blocking on the corridor wall side. Moreover, there was clear indication that this passage had a side passage coming off it to the south and connecting to room [1200], but this passage had been blocked off at some point too while [1266] was still open. Until more work is done next season, the full sequence will remain hypothetical, but enough has been exposed to support the idea that room [989] has an earlier phase.

The room [989] measures 9.3 m long by 3.5 m wide, though the walls are not in good condition, mostly due to later robbing when the room was re-built in the $19^{\text {th }}$ century. Just offset from the southern wall, there was a square cobbled stone platform [934], that was at first thought to be the footings for a fire place, but there was very little ashy material to confirm this; alternatively, it could be a hard standing for a ladder/steps up to an upper storey, which is know to have existed in the $18^{\text {th }}$ century. The floor layer in the room [1284] was extensive and composed heavily of wood chips and was fairly artefact-rich. There was probably a drain at the eastern end of the room; the drain which was associated with the $19^{\text {th }}$ century re-building of the room was assumed to be a single feature [499], but it now appears that its eastern end was originally cut much earlier; this is evident both in a change in the nature of the cut and the fact that it both continues into the blocked in passage [1266] and connects to yet another drain in another blocked in passage in the south wall of the room. This other passage [816] was probably blocked sometime in the life of room [989] - it is not shown on the 1784 plan, so must have occurred by this time. Floor layers [1167] and drain fill [1185] in the passage were associated with mid $18^{\text {th }}$ century finds, so it probably went out of use not long before 1784. However, when the passage was constructed is another matter.

The drain [1285] in passage [816] was a very unusual feature; although there was a slight cut, this may have been erosion from running water. On the whole, the sides of the drain were built up with long, squared timbers, packed behind with turf/soil and capped with flagstones. Sitting directly beneath the western timber was a coin minted in Brunswig in
1648. This may well be a foundation deposit since it is so fortuitous; nevertheless it provides a terminus post quem. It is unlikely the passage is original to this or the southern room however, as there was already an earlier passage connecting the two - that which ran from passage [1266] discussed above into the southern room. It may be that passage [816] was constructed when the latter passage was blocked in, thus altering the access routes between the rooms and the main corridor.

Figure 8. Timber lining for drain in passage [816]

Room [1200] (Library \& Offices; BL/ÁE/AH)

The room to the south of [989] and connected to it via passage [816] has an equally long sequence of occupation and re-building, also continuing into the $19^{\text {th }}$ century (as [443] \& [329]). This year, work began on the $18^{\text {th }}$ century levels of the room, and most time was
spent on excavating the upper floor [932], which was excavated in paired metre segments for artefact control. Beneath this layer were various turfy layers ([1196], [1228], [1238], [1206]), which may have been either earlier floors (as they were artefact rich) or part of a leveling layer that has disturbed earlier floors. These layers certainly seem to belong to a different construction phase as they run under the eastern wall of room [1200]. Until further work is done, little can be said about the layout of this earlier room but it does appear to have a drain system, which connects to that in passage [816]. Certainly this passage was blocked in when floor [932] was deposited, suggesting that we have only excavated the later phase in room [1200]. Based on the dating of associated artifacts, floor [932] is late $18^{\text {th }}$ century, which puts it at the very end of the sequence, while the earliest levels excavated so far in this room only date as far back as the early-mid $18^{\text {th }}$ century. There is clearly much more work to do here to get back to the $17^{\text {th }}$ century room.

Figure 9. Excavation of room [1200]

West of rooms [989] and [1200], work is still on going in $19^{\text {th }}$ century levels, so nothing can yet be said of the earlier rooms here. However, west of room [39], a room aligned at right-angles to it was exposed in 2003 which at first was thought to be pre-1630. This room [691] and associated passages [421] does not correspond with any buildings on the two extant $18^{\text {th }}$ century plans; indeed it lies where a miðbaðstofa and later chambers are marked on such plans, but these buildings (which are probably the same) are oriented the other way, parallel to room [39]. This building which pairs with [39] is presumed to have been completely destroyed leaving no traces, probably in the $19^{\text {th }}$ century. Indeed, the floors of room [691] and passage [421] produced nothing but $17^{\text {th }}$ century material.

## Room [691] (ÓS/GH/MS)

The room was 7.3 m long by 2.5 m wide, but both the walls and floors [1286] were very poorly preserved. Nevertheless, most of the post pads, which mark roof-supporting timbers were present, and beneath the floor layers a capped drain [1282] was recorded. This season only the overlying turf collapse deposits and the floor were excavated. The room had two doorways, on the north and south walls, the northern doorway leading to an outside alley between the building and the main complex to the north, and the southern doorway leading into a passage [421]. The drain [1282] also fed into this passage. The passage runs south, beyond the southern limit of excavation, but also has a side passage coming off it to the west, which connects to the adjacent room [1101].

Room [1101] (?Kitchen; CJVH)

Room [1101] is as yet, still not fully defined but seems to be oriented east-west and covers an area c. 8.9 m by $4.6+\mathrm{m}$, though the southern wall lies beyond the current limit of excavation. The room is badly disturbed and had various modern leveling dumps over it, and as yet, only these layers have been excavated, with the exception of a drain [1281]. This drain has at least two major phases of use; the upper drain fill contained finds from the early $19^{\text {th }}$ century, while the lower fill contained no dateable material. There also appear to be two phases of wall associated with the structure on the northern side at least,
the later wall being the more northerly and probably associated with the later phase of the drain. At present, this building is the least understood, and undoubtedly comprises at least two phases; given its position, this building seems likely to be the kitchen as marked on the two $18^{\text {th }}$ century plans, but was possibly also still in use in the early $19^{\text {th }}$ century where a building marked as a store stands.

## Phase 3 (1784-1896)

With the earthquake in 1784 and the relocation of the see and school to Reykjavik the following year, the settlement at Skálholt entered a new phase. Of the complex of buildings discussed in the previous phase, some appear to have been abandoned almost immediately - namely the school, but the main corridor, the infirmary and store room and the western wing, which included the Bishop's rooms, probably continued in use for some time, with minor modifications, such as sealing off abandoned rooms (e.g. the whey store and passage into dormitory and school). Within a short time however, the corridor and infirmary were probably also abandoned, and generally it was only the western wing of the complex that survived into the early-mid $19^{\text {th }}$ century. Much of the $19^{\text {th }}$ century phases of the site were excavated and discussed in last year's report (see Report no.2), including the re-use of the rooms [15] and [55] (Inner Chambers and Library/Offices). This season, work began on the western side of the western wing, where the $19^{\text {th }}$ century phase of the buildings were investigated, including a central corridor and a pair of westernmost rooms. It is also worth noting that the current stone verge of the car park just north of the site is probably part of the original edge of the $19^{\text {th }}$ (and $18^{\text {th }}$ ?) century farm (Figure 10).

Phase 3 (c. 1785-1896)

Figure 10. Phase 3 features

Passage [775] (Corridor; LBP/SGB)

A central passage or corridor bisects the $19^{\text {th }}$ century farmhouse, and was originally part of the $18^{\text {th }}$ century western wing, though at present only $19^{\text {th }}$ century levels have been excavated. The corridor was in its upper levels, fairly badly disturbed so the original surface is unclear, but within the length of the corridor was a linear deposit of turf and flagstones, mixed with ash layers [1035], which included many finds, dating to the late $19^{\text {th }}$ century. Beneath that was a slightly less disturbed floor surface of flagstones and ash ([1181], [1158], [1172], [1176]) with further $19^{\text {th }}$ century finds. There was a central drain [1287] running through the corridor but it too was badly disturbed; it was only excavated in the southern half. The drain was a central conduit into which drain from the various side rooms fed; where it exits the corridor to the south, it kinks to the southwest and appears to connect to the later use of the drain associated with room [1101] discussed in phase 4 (see above). The external area south of these buildings is surfaced with rough, large stone cobbles. To the north, the drain continues beyond the limit of excavation but a capstone is still visible under the grass and the drain can be traced up to the stone-lined verge of the car park.

Room [1288] (Stores; DT)

On the west side of this corridor opposite room [15] is another room of similar size; little has been exposed of it this season, as most time was spent excavating the cellar of the $20^{\text {th }}$ century farmhouse which has truncated a large part of the room (see phase 2 below). The room is marked on the 1836 plan as stores (for meat and dairy at the western end and peat and dung on the east, doubling as a kitchen with a stove.

Room [1174] (Workshop; GML)

The adjacent room to the south, and opposite room [55] was better preserved, but the plan of the room remains unclear still. A drain [1198] appears to run between a connecting passage between this room and [1288] to the north, dog-legs to the east to run into the
main drain running down the central corridor. This is completely at odds with the plan from 1836, but it may be that this drain was originally part of the $18^{\text {th }}$ century rooms, retained into the early $19^{\text {th }}$ century before modifications. Finds from this feature date to the early $19^{\text {th }}$ century.

## Phase 2 (1896-1958)

The last phase of occupation on the site is marked by the building of a new farmhouse and farm buildings at the turn of the $20^{\text {th }}$ century (Figure 12). Many of the farm buildings were excavated in 2002 and 2003, largely with a machine as they had been backfilled with stone rubble, and these include the haybarn [002], silo pit [635] and an adjacent byre [745] (see Report no.2). A thick, artefact-rich sheet midden spreading south of the byre as well as a pair of pits [750] containing both articulated and disarticulated animal bones were excavated by hand in 2003 and completed this year. In addition, two drains in the base of the haybarn were excavated by hand; the first [181] was largely excavated in 2003 and ran from the center of the barn, dog-legged to the south and outside. It shows two phases, initially stone-lined, later with an iron pipe installed; originally it was thought the earliest phase was contemporary with the original building of the barn but it now seems that this early phase dates to the $17^{\text {th }}$ century and is part of the system from the dormitory. The other drain [1139] runs along the southern edge of the barn and is a simple stone-lined feature.

The main farmhouse lies to the northwest, and what survives is solely the cellar [1098], whose south-east corner just projects within the northern limit of excavation. Local memory indicates that $0.4-0.6 \mathrm{~m}$ of the surface was bulldozed away when the farmhouse was demolished in the late 1950s, and it seems as if only the cellar of this building may have survived. The cellar was stone-lined and cut down from the present surface at a depth of 0.6 m ; it had a damaged, flagstone floor over a drain, and was infilled with demolition material, including a large assemblage of mid- $20^{\text {th }}$ century finds.

Figure 11. Some of the finds from the cellar

Phase 2 (c. 1896-1958)

25m
Figure 12. Phase 2 features

## Midden Area

Although the main focus of excavation is on the settlement core, more limited investigations have been initiated on the southern edge of the farm mound, where midden deposits were located last season. Two areas were excavated this year; the first was an extension of a small $2 \times 2 \mathrm{~m}$ trench [383] opened last season, which was expanded south and westward (3x1m) to increase the quantity of animal bone retrieved from a localized dump [753]. This season, another substantial assemblage of bone was recovered, and the deposit seems to continue - and even thicken westward, suggesting this is only the eastern edge of a more extensive bone dump. The other trench was placed further east, on the edge of a major promontory which is marked on the 1784 plan as an ash mound [634], in order to acquire a more general sequence of discarded material culture. A 3x8m trench [1070] excavated multiple layers of ash dumps, and while it retrieved a finds do however date firmly to the $18^{\text {th }}$ century; while only the very upper layers have thus far been excavated, it is hoped that as excavation proceeds deeper in later seasons, more artefactrich layers will come to light.

Figure 13. Expansion of the bone dump test pit [383]

## Finds

Over 222 kg of finds were retrieved in 2004, comparable to the previous season - these include c. 9800 individual fragments of pottery, glass, clay pipe, metal, stone and other artifacts (but excluding most organics such as wood, bone and textile). A summary breakdown is given in Table 1. The finds date from all periods between the early $17^{\text {th }}$ and mid $20^{\text {th }}$ century, but with the larger portion being earlier. All finds were cleaned and repackaged after excavation, related groups assigned finds numbers in continuous sequence from last year (in arrow brackets on the bags, e.g. $<7843>$ ) and entered into the project database. Metalwork and organics requiring conservation were sent to the National Museum where they remain in storage until further study. The report below gives only a basic assessment of the finds, organized by material category. Full analysis, as in previous years, will occur after completion of the excavation.

## Organic

As in previous seasons, preservation of organic remains was very good, and was particularly so in the waterlogged levels at the base of the main corridor. The bulk of the organic remains were animal bone, generally butchery and food waste, a large part of which (c. 22 kg ) came from the midden test trenches, but fairly substantial amounts of c . 10 kg each also from the drain [1117] in the corridor and the upper floors in room [1200]. The amounts here are both startling and raise many questions about depositional practices - analysis of the bones themselves will hopefully shed some light here. There was no worked bone recovered save one fragment of a bone comb <4655>. Wood was also a major portion of the organic material, almost as much by weight as bone; by far the majority was structural timber and most of this deriving from the wheystore [887]. Besides these however, there were many wooden artifacts including part of a comb, a carved knife handle, 40 buttons, 4 gaming pieces, and numerous elements of stave vessels. Woolen textiles were fairly abundant especially from the corridor drain [1117], mostly as scraps of woven fabric but a fine, possibly knitted mitten was also retrieved
$<4156>$ (Fig.1). Fairly large numbers of textiles also came from the wheystore [887] and room [901]. Leather scraps were also frequent, especially from the corridor drain [1117], and rooms [1200] and [901]. Other organic finds occurred in smaller quantities such feather, horsehair, horn, shell and wax.

Figure 1. Knitted mitten from the corridor

Ceramic

Ceramic building material, specifically bricks, was retrieved in fairly large amounts, generally from the later phases and especially in large amounts from the cellar of the $20^{\text {th }}$ century farmhouse [1098] and also from the corridor [775]. Pottery was as abundant as previous seasons, and occurred in all phases, large amounts coming from the corridor [775] but also substantial quantities from the corridor drain [1117] and the cellar [1098]. The range of wares is by now fairly familiar; for the later phases 2 and 3 , industrial
whitewares predominate, often decorated with transfer-print designs, but spongewares and factory slipwares are also common. In the earlier $19^{\text {th }}$ century, glazed red earthenwares, often with slip trail decoration occur alongside some late tin-glazed earthenwares; a particularly large tin-glazed plate $<4960>$ with blue spatter sponge in the center came from deposits associated with room [1288]. Later porcelain was present, though not in large numbers; several pieces of the fluted blue or onion pattern occurred, almost certainly from the Copenhagen factory. Earlier ceramics include the ubiquitous Chinese export porcelain, much of it with external brown enamel, but otherwise the basic blue and white decoration, though a few enameled pieces occurred. Large parts of a saucer came from room [127] and also from room [1200], the latter with brown, hardened residue indicating the vessel had been re-used, perhaps for some craft purpose. Various coarse, glazed earthenwares also occurred in earlier phases, but German stonewares were numerous - especially Westerwald and Frechen bottles, but also enameled ware more common last season. Earlier tin-glazed wares also occurred, many dating to the $17^{\text {th }}$ century.

Clay pipes were as numerous as the previous season and a substantial part were from the $17^{\text {th }}$ century. Almost all appeared to be Dutch as previously. Many bowls were marked and a few stems, providing good dating material for the deposits. Stamps included the snake (very common), milkmaid, crown, rose, swordsman, and key; many bowls also had quality marks, either the Gouda shield on the heel side or dots (commonly 7) on the bowl side. Several stems had moulded decoration, one with a crocodile on the stem; plus the various usual rouletted decorations on stems. Actual name stamps include one stem marked M.VERZY..., a bowl with the initials EB under a crown, and a stem marked LUCKAS. One unusual fragment <5093> showed signs of probable repair - the junction of the bowl and stem had a collar of lead wrapped around it. Apart from the standard clay pipes, there were several more unsual types. These include two fragments of detachable glazed pipe bowls, probably from the $19^{\text {th }}$ century and a third, ornately moulded but unglazed detachable bowl <5043>, also probably $19^{\text {th }}$ century.

## GLASS

The majority of glass comprised vessels, chiefly bottles and a large part of which came from the cellar [1098]; local memory attests to the presence of a bottle collection in the cellar of the farmhouse, and a large number of the bottles were complete and in many cases, still intact. Bottles included many kinds, such as soda/beer bottles, medicine bottles and several coca-cola bottles, the latter dating from the mid 1950s. However, some large quantities of glass fragments also came from the drain [1117] in the corridor, including phials and wine bottles. Apart from bottles and phials, there were also glass tablewares including painted/enameled flasks, blue-flecked latticino vessels, and an engraved stemware/tumbler. After vessel glass, window glass was the next most common; the largest portion came from the cellar [1098], but substantial amounts also came from room [1200]. The glass was either blown and greenish in the earlier layers, or machine rolled and clear in the later phases. Finally there were also a few glass artifacts, notably 15 beads and 15 buttons.

Metal

Iron objects comprised the largest portion of metal finds by far, of which the vast majority were nails (over 1000). Others included structural ironwork such as hinges, a lynch pin, staples and wire fragments. Among the identified objects were five knife blades, a fork, key, and two pairs of scissors. Copper alloy was the next most common metal find, and these included various dress fittings (58 buttons, an eyelet), two book clasps, a pendant, seal, thimble and various fittings such as tacks, roves and small nails. Other metal work included pewter (36 buttons inter alia), lead (including a cloth seal and a weight), and a silver and gold coin. Both precious coins were Danish, Frederik IV, the silver coin $<3686>$ from 1702 and the gold $<3642>$ from 1714. At least one other coin was found, a Ferdinand III from Brunsvig, dated 1648 in silver or copper alloy <3758>.

Stone

The most common stone artifacts were flints, mostly chips from the 'chards' used with strike-a-lights, which have been common every season. Other worked mineral stones retrieved including jasper and obsidian probably had a similar function. By weight, the most numerous finds were heavy duty basalt objects, chiefly fragments of quernstone (4), grindstone (2) and a fish hammer. Other common stone artifacts include schist whetstones (59 fragments), slate roof tile (27), and fragments of quartz, pumice and graphite and amber.

## Other

One plastic object was retrieved (from a deposit associated with the $20^{\text {th }}$ century farm) and a few composite finds, including a copper alloy book clasp with leather attached <3684> and a copper alloy button with wooden core <3628>.

# Preliminary Report of an Analysis of Faunal Remains from an $18^{\text {TH }}$ CENTURY MIDDEN AT SKÁLHOLT, ICELAND 

George Hambrecht (CUNY Doctoral Program in Anthropology)<br>Peter Kuchar (REU, Research Expirience for Undergraduates, Hunter College, NY)<br>Dr. Jim Woollett (Dépt. d'histoire, Université Laval , Québec, Canada)

#### Abstract

This report presents results of a preliminary analysis of the mammal bones from one context in an $18^{\text {th }} \mathrm{c}$ midden at the Episcopal farm of Skálholt, Arnessyslá, south Iceland. This context (454) was part of Midden Test D (Group 383), and was excavated by Dr. Jim Woollett, Matthew Brown, and Kate Krivogorskaya during June and July of 2003. Further excavation of this context was conducted by George Hambrecht during June of 2004. Details of excavation and recovery methodologies employed, as well as descriptions and discussions regarding the complete stratigraphy of Midden Test D and other midden test pits undertaken at Skálholt in 2003 can be found in reports of field work by Woollett (2003) and Lucas (2004). This work was conducted as a midden sampling program, in conjunction with the FSI excavations of the $18^{\text {th }}$ century phase of Skálholt. A total of 20,554 bone fragments were recovered from Context 454, representing roughly one half of the total number of bone fragments recovered from the entire site in 2003 and 2004. The remaining half of the 2003 and 2004 assemblages are derived from a great number of contexts in the house and various midden tests, many of which contributed single bag bone samples. An analysis of faunal remains from these other contexts is on-going and is not discussed in this report. All sediments were dry sieved through 4mm mesh to standardize recovery of bones following usual NABO recommendations. This assemblage does not fit the typical dairy survivorship profiles associated with North Atlantic farm economies. The majority of these cattle were slaughtered at their peak age for meat return, sometime before the second half of their third year of life. This assemblage seems to represent a high cost, and high value beefcattle strategy rather than the more usual dairy pattern of peaks in mortality in very young

and very old animals. This assemblage could also be the product of the culling of unproductive milk cows for meat. Yet the almost total absence of neonatal cow bones, as well as the few indicators of the presence of very old cows suggests that the meat strategy is a more likely explanation. A meat based strategy calls for large amounts of pasture land and winter fodder. It is a strategy that invests these assets towards a one-time meat return, as opposed to long-term dairy production. In the Icelandic context in any period such a strategy would be exceptional (McGovern, et al 2001). Archaeofauna from the $9^{\text {th }}-$ $11^{\text {th }}$ c contexts from Sveigakot and Hofstaðir in Mývatnssveit, and the $18^{\text {th }}$ century from Finnbogastaðir in NW Iceland will be used for the purposes of comparison.

The cattle represented in this context seem to have been of a breed foreign to Iceland that must have been introduced from continental Europe. All the crania recovered from this context are polled. In all but two of these cases the cattle were naturally polled. In the other two cases the cattle were artificially polled. Cattle in Iceland from the Settlement Period through the Early Modern Period were of horned varieties. Naturally polled cattle were a rare genetic mutation that appear very infrequently in the archaeological record. The appearance of this different breed suggests that these cattle might have been part of an effort towards agricultural improvement on the part of the Bishops of Skalholt. The appearance of the artificially polled cattle suggest how the urge towards improvement went beyond pure economics and entered the realm of fashion and identity.

## Site Context

Context 454 is a midden deposit broadly dated to the first half of the eighteenth century, at which time Skálholt was a large, proto-urban settlement and the diocesan headquarters for southern Iceland. The midden containing context 454 was, according to contemporary maps close to, and possibly associated with, a butcher's work shed. Butchery related artifacts such as a piece of whale bone butcher block and a possible whale bone knife handle were found in context 454. It is also located alongside the edge of a roadway that ran through a complex of outbuildings south of the Bishop's residence. The midden was formed through a series of dumps of refuse, ash and fill over the edge of the road.

Context 454 was the only context in this midden associated with quantities of wellpreserved, whole animal bones. It is an extremely dense midden deposit, with very little sediment present between the closely-packed and entangled bone fragments. Because the edges of adjacent, thin peat ash deposits interdigitate with it, context 454 seems to represent an accretion of multiple dumps occurring over a fairly short time period.

## Laboratory Methods

Analysis of the Skalholt collection was carried out at the Brooklyn College and Hunter College Zooarchaeology Laboratories and made use of extensive comparative skeletal collections at both laboratories and the holdings of the American Museum of Natural History. All fragments were identified as far as taxonomically possible (selected element approach not employed) but most mammal ribs, long bone shaft fragments, and vertebral fragments were assigned to "Large Terrestrial Mammal" (cattle-horse sized), "Medium terrestrial mammal" (sheep-goat-pig-large dog sized), and "small terrestrial mammal" (small dog-fox sized) categories. Only elements positively identifiable as Ovis aries were assigned to the "sheep" category, with all other sheep/goat elements being assigned to a general "caprine" category potentially including both sheep and goats. Following NABO Zooarchaeology Working Group recommendations and the established traditions of N Atlantic zooarchaeology we have made a simple identified fragment count (NISP) the basis for most quantitative presentation. Measurements (Mitoyo digimatic digital caliper) of fish bones follow Wheeler \& Jones (1989), mammal metrics follow Von Den Dreisch (1976) and mammal tooth eruption and wear recording follows Grant (1982). General presentation of domestic mammal age reconstruction follows Enghoff (2003). Digital records of all data collected were made following the $8^{\text {th }}$ edition NABONE recording package (Microsoft Access database supplemented with specialized Excel spreadsheets, see discussion and downloadable version at www.geo.ed.ac.uk/nabo) and all digital records (including archival element by element bone records) and the bone samples are permanently curated at the National Museum of Iceland. CD R versions of this report and all archived data are also available on request from nabo@voicenet.com.

Butchery marks are numerous and variable on this assemblage. A large amount of measurements were also recorded. These aspects of the assemblage will not be addressed in this preliminary report, but will be addressed in later reports drawing on a larger portion of the whole archaeofauna.

## Overview of Species Present

Table 1 presents a count of the identified specimens (NISP 4,227) and the less well identified categories of "Large Terrestrial Mammal" , "Medium Terrestrial Mammal" and "Small Terrestrial Mammal" and unidentified mammal bone fragments which contribute to the overall bone count (TNF) of 20,554.
Domestic Mammals Count
Cattle (Bos taurus) ..... 887
Horse (Equus caballus) ..... 3
Dog (Canis familiaris) ..... presentSheep (Ovis aries)27
Caprine (Sheep and Goat) ..... 118
Total Caprines ..... 145
Total Domesticates ..... 1035
Cetacea ..... 2
Arctic Fox (Alopex lagopus) ..... 2
Fish sp to be determined ..... 2203
NISP total ..... 4277
Large Terrestrial Mammal ..... 888
Medium Terrestrial Mammal ..... 94
Small Terrestrial Mammal ..... 1
Unidentified mammal fragment ..... 15,294
TNF total ..... 20,554

Table 1. Species NISP

Horses are represented by a whole metatarsus, which may represent raw material for craft work rather than meat waste, though there is also a molar and a fragment of a horse scapula. Dogs are represented by tooth marks on bones, and were certainly present on site
despite the absence of their remains from this context. The tooth marks could also have been made by Arctic Fox which is present in the context. Birds are not present in the current sample. Species and element identifications for the fish elements are currently underway and will be presented in a later report.

## Domestic Mammals

Table 2 presents the count of fragments (NISP) and relative \% of the domestic mammals. Cattle dominate the domestic mammal assemblage; no other currently known archaeofauna from Iceland has such a high percentage of cattle bone. Caprines together make up less than $15 \%$ of the deposit.

| Cattle (Bos taurus) | 85.00 |
| :--- | ---: |
| Horse (Equus caballus) | 0.30 |
| Dog (Canis familiaris) |  |
| Sheep (Ovis aries) | 4.00 |
| Caprine (Sheep and Goat) | 11.00 |
| Total Caprines | 15.00 |

Table 2. \% NISP of Domesticates

Of the unidentifiable mammal bones, LTM (large terrestrial mammals) make up a similar majority in proportion to MTM (medium terrestrial mammals) and STM (small terrestrial mammal) as cattle to caprines in the NISP. Considering that equids are represented by only three elements, and that the proportions between bos versus other mammals and LTM versus MTM (medium terrestrial mammal and STM (small terrestrial mammal) are similar it might not be too risky to associate LTM with cattle.

Finding cattle at a high status site such as Skálholt is not out of the ordinary, but to find an assemblage so totally dominated by cattle is. In comparison, archaeofaunal assemblages from the medieval farm sites of Sveigakot and Hofstaðir in the north of Iceland exhibit far higher numbers of caprines, with cattle routinely representing between
$15-20 \%$ of the archaeofaunal assemblages in the early period after landnam, and then falling to $10-15 \%$ later in the early medieval period (McGovern et al 2001, Perdikaris et al 2004). The archaeofaunal assemblage from a lower ranking $18^{\text {th }}$ century site in NW Iceland, Finnbogstaðir, has cattle making up roughly $10 \%$ of its assemblage (Edvarsson et al, 2004).

## Element Distribution

The chart below (Figure 1) shows the percentage MAU (Minimum Animal Unit). MAU illustrates element distribution within the assemblage (Grayson, 1984). Vertebral elements, excepting the axis and the atlas, are left out as they are not species identified, but LTM vertebral elements are present in significant numbers.

## Cattle Element \%MAU

Figure 1 Percentage of MAU for cattle

The element distribution for the cattle strongly suggests that these cattle were slaughtered onsite. Elements from across the whole cow are present. If the beef represented by this archaeofauna was being imported in from surrounding farms or regions, our element

MAU would most likely contain a majority of heavy meat bearing bones, such as the femur and humerus. The fore and hindquarters with heavier meat loads, represent almost $40 \%$ of the MAU. Yet the rest of the assemblage does contain very low meat bearing elements such as phalanges and metapodials from the lower fore and hindlimbs, whose presence does imply that many of these cows were slaughtered onsite.

## Mortality/Age Structure of Cattle

A number of approaches have been applied to archaeofaunal assemblages to determine the age at which animals were killed in an effort to reconstruct herding strategy (Payne 1974). The presence of newborn (neonatal) bones, tooth eruption and wear, and fusion state of long bones are all usually combined in an attempt to reconstruct the mortality profile (Enghoff 2003).

The cattle in the context 454 collection are almost all adults or older juveniles (table 3). Neonatal bones are barely represented in this assemblage but normally make up 20-40\% of most Icelandic farm collections from all periods.

| Cattle Bones | \# of bones | \% |
| :--- | :--- | :--- |
| Adult \& juv | 887 | 99.66 |
| Neonatal | 3 | 0.34 |

Table 3. Adult/Juvenile and Neonatal Cow bones

Tooth eruption patterns observed on both maxillary and mandibular cattle tooth rows, Figure 2, indicate that the majority came from young adult animals.

## Skalholt Cattle Tooth Eruption

Maxilla included

Figure 2 Cattle Tooth eruption

Cattle M3 Wear

* \# of elements

Figure 3 M3 wear on cattle

Figure 3 presents the wear state of the cattle maxillary third molar, erupting when the animal has become fully adult. The majority of these erupted third molars (M3) show very light to medium wear, suggesting that the majority of these animals were young adults rather than very old dairy cattle reaching the end of their useful lifespan. The significantly larger number of maxillae compared to mandibles means that this analysis will use maxillae wear state as an indication of age instead of only relying on Grants age estimation method.

Skalholt Cattle MWS - Context 454

Figure 4 Mandible wear state on cattle

Figure 4 presents the mandibular wear state for the available cattle jaws, making use of the Grant (1982) method, age estimates relative to tooth eruption and wear from Grigson (1982).

Light and medium wear account for roughly $84 \%$ of the sample of maxillary tooth rows (out of 44 samples). This strongly suggests that these cattle were slaughtered when they were three years old or older (Grigson, 1982). The significantly smaller number of M3 showing heavy wear suggests that there were few older animals, meaning older than 4-5
years, represented in this dump. The mandibles tell a similar story, suggesting that the majority of the cattle represented by unit 454 lived until sometime after their third year. Yet due to the much larger sample size of maxillary tooth rows, the M3 maxillary tooth wear data should be emphasized over the mandibular tooth wear data, with its much smaller sample size ( 7 mandibular tooth rows). Also, dental wear is a relative indicator of age. Different levels of erosion and pasture fertility can, for example, either inhibit or increase the levels of tooth wear in a cow. In order to lessen the "noise" from such possible variables the fusion state of selected long bones must be examined as well.

The fusion states of the cattle long bones reinforce the idea that these cattle lived beyond their third year, but not much longer than their fourth year (figure 5).

## Cattle Long Bone Fusion <br> * \# of elements

Figure 5 Long bone fusion on cattle

As can be seen from the above chart $38 \%$ of the cattle in this assemblage had unfused distal femurs by the time they were slaughtered. This fusion does not happen until
sometime in the second half of their third year of life. $62 \%$ of the distal femoral ends are fused. This is the largest proportion of unfused long bones in this sample. Coupled with the tooth wear data this reinforces the idea that this assemblage is the product of a meat producing sector of Skálholt's economy. Slaughtering cattle in the second half of their third year would probably take them at or near the peak of their growth curve, before they could become effective milk producers but near the point where further feeding produced little or no increase in carcass size (Payne 1974). Dedicating valuable fodder towards the raising of full sized cattle is a high status investment. In a zooarchaeological assemblage from dairy economies of less wealthy, though by no means poor farms in Iceland, one finds a large amount of bones from neonates and then again from older animals, past their prime (McGovern, 2003). The older cows represented in the assemblage, such as the $62 \%$ fused distal femoral ends, and possibly the heavier wear on the maxillary M3's, could be the culling of less productive dairy cattle. Yet the long bone fusion and tooth wear data together point towards a meat producing husbandry strategy.

Data from McGovern 2003
Figure 6. Early Medieval Dairy Pattern

For the purposes of contrast, examples from the site of early medieval sites of Hofstaðir and Sveigakot illustrate the dairy pattern well (Figure 6). In both these cases we see large scale culling of young cattle soon after birth, reserving available grazing for the adult dairy cattle (and their mother's milk for human consumption). At Hofstaðir, a relatively high status site, it seems that a small number of cattle were allowed some time to grow for greater meat productivity. In both cases we also see evidence of very old cattle, which were presumably females slaughtered after they had exceeded their prime milking years.

A detailed presentation of the caprine mortality profiles will follow in later reports.

## A Continental European Breed of Cattle?

All of the cattle crania ( 10 skull elements in which the horn core area was intact) recovered from context 454 are polled. 8 of these crania were naturally polled (Figure 7), 2 were artificially polled. In one of the artificially polled examples infection set in after the removal of the horn (Figure 8). Settlement period and medieval Icelandic cattle breeds were horned, as were contemporary cattle in Greenland and Shetland, though naturally polled (hornless) animals appeared in low frequency across the region ( McGovern 1985, McGovern, Perdikaris et al 2001). Medieval Icelandic law defined a legal tradable cow as having horns:
> "Also of standard value is a cow three winters old or older, ten winters old or younger, capable of bearing calves, in milk, horned and free of defects, no worse than the average beast, fit enough to be driven from one district to another at the moving days and giving enough for a calf at milking. She is a valid form of payment." (Grágás K246, Dennis, Foote, \& Perkins Transl. 2000 vol II, p208)

The appearance of substantial numbers of naturally polled cattle strongly suggests an early modern introduction of a European continental variety.

Figure 7. Note smooth frontals without horn core or removal scar.

Figure 8. Note scarring and bone reaction to infection.

## Discussion

Context 454 seems to represent the product of a meat producing sector of Skálholt's economy. The majority of the cattle represented were slaughtered at a prime age for meat procurement versus fodder investment, as we can see in the tooth wear data and the long bone fusion percentages. Those older cattle represented could have been unproductive milkers, or the product of herd population management culling. As context 454 is a relatively small sample, in comparison to the size of the site of Skálholt, it should be assumed that this midden only represents one small part of one sector of the Skálholt economy. As the context is indicative of a beef cattle producing profile, this assemblage might then be the product of the nearby butcher, or of some specialized beef processing or consuming sector of the Skálholt population. Coupled with this exceptional zooarchaeological profile is the presence of what looks like an introduced continental European breed of cattle. The Bishops of Skalholt were not only showing their wealth and power through their meat based cattle economy, but also through their desire to possess a different cattle breed than the rest of the Icelanders. Considering the absence of these cattle in the contexts above 454 what we might be looking at is a failed experiment on the part of the Bishops of Skalholt. These cattle might have been an attempt at both starting a dedicated beef economy as well as an attempt to make the landscape of Skalholt look more "improved" in the $17^{\text {th }}-18^{\text {th }}$ century European sense of the word (reference). The presence of both the continental European cattle breed as well as what might be native Icelandic cattle physically altered to look more like this new polled breed bring up questions regarding Skalholt's place in Iceland's cultural landscape and its sense of its own identity. This issue as well as the rest of the zooarchaeological assemblage of Skalholt will be investigated in later publications.

## Resistance survey

Arnar Már Vilhjálmsson

Between July 15th to 17th, an earth resistance survey was conducted west of the Skálholt church and archaeological investigation areas of 2002-2004 (see Figure 1). The aim was to see if archaeological remains could be located in this area.

Figure 1. Skálholt. The thick lines represent the grid squares and the survey area is shaded.

A grid of $20 \mathrm{~m} \times 20 \mathrm{~m}$ squares was established over the investigation area and this grid was surveyed using a Geoscan RM15 resistance meter. Twin probe configuration was
used, see Figure 2, where the mobile probe separation was 75 cm . Traverses had a spacing of 1 m and readings were collected at 0.5 m intervals along traverses.

Figure 2. Twin probe configuration

Electric current is passed through the ground and the resistance measured. The amount of resistance is affected by how much moisture is in the soil. If there is a ditch or pit that can store more moisture we get low resistance as the electric current passes easier through the wet ground. On the other hand, if for example a stone wall is present under the surface there is less soil to store moisture and therefore the resistance gets higher. By turning these readings into an image, buried walls and dykes etc. (if there are any) often show up as trends in that image.

In order to interpret the readings the resistivity data set was exported to a computer and processed. The processing includes coordinate correction, filtering and interpolation. MATLAB R13 (© 1984-2002 The MathWorks, Inc.) was used to arrange the data and make simple corrections. Surfer 8 (© 1993-2002 Golden Software Inc.) was then used to plot the data, interpolate and filter.

## Results

In Figure 3 are the results of the resistance survey. In Figure 3(a) is the data as it came out of MATLAB with additional interpolation in Surfer. Figure 3(b) shows the readings filtered with 7 x 7 difference of Gaussian filter where the high resistance areas and contrasts have become clearer. The images show some trends but the results are overall
rather poor and that might partly be due to patchy rain during the survey days and disadvantageous conditions in the soil.

Most of the high resistance is found in the central area and the most striking anomaly is the semicircle which starts there and ends in the northern part (Figure 3(c)). The semicircle is cut by a strong trend in one place and there are also two strong trends parallel to the survey lines and one perpendicular. Then we have many anomalies that are not as clear (dotted lines) in the central and west part. It is possible that more such trends are present but any further delineation would be ambiguous. The high resistance at the top of the figures shows a clear anomaly and in the southeast corner we also see good lines. The lineation that lies NNE-SSW in the southeast corner is cut in half by a strong low resistance anomaly and this anomaly is most likely caused by a fence that enclosed the excavation area. In this SE-square we can also see a high resistance anomaly close to the left edge caused by deep grass which the probes barely went through.

Figure 3. Earth resistance survey at Skálholt. (a) Interpolated data. (b) Difference of Gaussian filtered and interpolated data. (c) Main anomalies lined out. The solid lines represent stronger trends than those represented with dotted lines.

## Discussion

This season has been incredibly successful in terms of fulfilling objectives and new discoveries. While the work unearthed some extremely rare and unusual finds - such as the gold coin (probably one of only a handful known in existence, anywhere; Anton Holt, pers.comm.) or carved wooden gaming piece - it is the complexity of the architecture that continues to challenge and surprise. Part of this is no doubt due to the powerful impressions given by historical maps of Skálholt, which while on the whole, are being confirmed by the archaeology, are also severely limiting. Not revealed in the maps (or even in documents) are the subtle and fairly frequent modifications made to the settlement, especially in terms of access and movement around the site. One of the key revelations this season has been the recognition of an increasing segregation between the western and eastern wings of the settlement; in the $17^{\text {th }}$ century, it seems access between the school on the one side and the Bishop's rooms, library and other rooms on the other was fairly open, with many connecting passages. Over the $18^{\text {th }}$ century, these seem to have gradually been closed off, and one by one, in piecemeal fashion rather than as a single event. This may reflect on a broader politics or social distinctions between the Bishop and School. More generally, alterations and changes to the buildings seem unsurprisingly perhaps - to have been a fairly common occurrence, with perhaps major phases of change occurring at least once if not twice in every century.

Another interesting aspect is the degree of discard or deposition of finds in certain rooms; certainly it now appears that most of the rooms where people slept have generally high artefact densities, but these finds are often explicable on the basis of cumulative loss buttons, beads, small fragments of pottery and glass which broke and were trampled into the floor. However in the main corridor there is a substantial amount of what appears to be working refuse - leather scraps, butchery waste, while in room [1200], there is an equally high number of finds. Until full analysis of the finds is complete, little can be said, and it is possible it may require some re-interpretation of the nature of the deposits.

However equally likely, it may indicate reviewing certain assumptions about the nature of activities and discard practices associated with different places in the settlement.

A third issue concerns the faunal data now coming from the midden test pits, specifically the evidence for progressive cattle husbandry practices by introducing foreign stocks and possibly even attempts to imitate such foreign breeds within the Icelandic stock. The role of Skalholt as an innovator in agricultural practices formed part of exploratory research conducted by Ian Simpson of the University of Stirling in the first season (2002), who examined soil profiles within the homefield for evidence of soil improvement. He found that there was intense manuring in post-Landnam soils which exceeded the 'normal' levels found at other sites in Iceland. Although this work was preliminary, it was suggested such strategies could be pre-Reformation in date. Given the major changes in agriculture in the $18^{\text {th }}$ century in England, especially in terms of livestock breeding, this new data adds another dimension to the role of Skalholt in Icelandic farming. It would clearly be beneficial to do further work on soils to refine the chronology of these improvements and establish the diversity of agricultural innovation in the postReformation period.

Remains of the earlier settlement at Skálholt - i.e. pre- c. 1630 - have only been seen at the eastern end of the site, under the school room and dormitory. In these areas, fragments of wall lines have been observed, but no overall pattern discerned; given the time available to the project as currently planned and funded, it is unlikely these can be further investigated. In the two remaining years anticipated, the main effort will be directed to completing the excavation of the core settlement back to its $c .1630$ level. This will involve continuing on the western side of the current area, and possibly expanding the excavation south, to incorporate the remaining 10-15 metres of the main corridor and the two southern wings which include the refectory, offices and stores. Outside this area, further work is still required on the midden slopes, both to extend and complete the new trench opened this year and if possible, conduct smaller test-trenching along the perimeter to see if there is any further localization of specific rubbish dumps. If time
permits, limited trenching may also take place on the printing house to the west and various storerooms and staff rooms south of the main complex.
